

Phosphorus silicon glass layer solar

Overview

What is phosphosilicate glass (PSG) layer?

Commonly, the dopant source grown on the silicon surface during the deposition step of POCl_3 diffusions is referred to as the phosphosilicate glass (PSG) layer. Actually, the PSG layer is separated from the silicon surface by a thin silicon dioxide (SiO_2) layer featuring a much lower phosphorus concentration .

How do phosphorus silicate glass layers affect PV efficiencies?

Phosphorous silicate glass (PSG) layers were carefully designed on an emitter layer to determine how they affect the efficiencies of solar cells before and after PID. A current-voltage (I-V) tester was used to determine PV parameters. An ellipsometer and transmission electron microscope (TEM) were used to measure the thicknesses of the PSG layers.

Can phosphorus silicate glass reduce the PID of c-Si solar cells?

Du et al. 25) have shown that the PID of c-Si solar cells can be effectively reduced without influencing their efficiency by inserting phosphorus silicate glass (PSG) layers between the front n + emitters and the SiN_x ARC layers.

Where is phosphosilicate glass used?

Present address: Global Photovoltaic Simulation Group, Case Postale 1056, 1211 Geneva 1, Switzerland. The phosphosilicate glass (PSG), fabricated by tube furnace diffusion using a POCl_3 source, is widely used as a dopant source in the manufacturing of crystalline silicon solar cells.
